Unit 2 - Physical Chemistry

CHEMICAL EQUILIBRIUM

Pupil Notes
Learning Outcomes & Questions
2. CHEMICAL EQUILIBRIUM

Reactions at equilibrium
2.1 A chemical reaction is at equilibrium when the composition of the reactants and products remains constant indefinitely.

2.2 The equilibrium constant (K) characterises the equilibrium composition of the reaction mixture.

2.3 The equilibrium constant can be measured in terms of concentration or, for gases, in terms of pressure.

2.4 For the general reaction $aA + bB \rightarrow cC + dD$

$$K = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

where [A], [B], [C] and [D] are the equilibrium concentrations of A, B, C and D, respectively, and a, b, c and d are the stoichiometric coefficients in a balanced reaction equation.

2.5 In a homogeneous equilibrium all the species are in the same phase.

2.6 In a heterogeneous equilibrium the species are in more than one phase.

2.7 The concentration of pure solids or pure liquids are constant and are given the value 1 in the equilibrium equation.

2.8 Equilibrium constants are independent of the particular concentrations or pressures of species in a given reaction.

2.9 Equilibrium constants depend on the reaction temperature.

2.10 Le Chatelier’s principle states that when a reaction is subject to change the composition alters in such a way as to minimise the effects of that change.

2.11 For endothermic reactions a rise in temperature causes an increase in K, i.e. the yield of product is increased.

2.12 For exothermic reactions a rise in temperature causes a decrease in K, i.e. the yield of product is decreased.

2.13 The effects of changes in concentration or pressure on the position of equilibrium can be explained quantitatively in terms of a fixed equilibrium constant.

2.14 The presence of a catalyst does not effect the equilibrium constant.
Equilibria involving ions

2.15 The Bronsted-Lowry definitions of acid and base state that an acid is a proton donor and a base is a proton acceptor.

2.16 For every acid there is a conjugate base, formed by loss of a proton.

2.17 For every base there is a conjugate acid, formed by gain of a proton.

2.18 The ionisation of water can be represented by:

\[ H_2O_{(l)} + H_2O_{(l)} \rightleftharpoons H_3O^+_{(aq)} + OH^-_{(aq)} \]

2.19 Water is amphoteric.

2.20 The equilibrium constant for the ionisation of water is known as the ionic product and is represented by:

\[ K_w = [H_3O^+] [OH^-] \]

2.21 The value of the ionic product varies with temperature.

2.22 At 25°C the value of \( K_w \) is approximately \( 1 \times 10^{-14} \) mol\(^2\) l\(^{-2}\).

2.23 A shorthand representation of \( H_3O^+ \) is \( H^+ \). Stoichiometric equations and equilibrium expressions can be written using \( H^+ \) instead of \( H_3O^+ \) where meaning is clear.

2.24 The dissociation in aqueous solution of an acid of general formula HA can be represented as:

\[ HA_{(aq)} + H_2O_{(l)} \rightleftharpoons H_3O^+_{(aq)} + A^-_{(aq)} \]

2.25 The acid dissociation constant of acid HA is given by:

\[ K_a = \frac{[H_3O^+] [A^-]}{[HA]} \]

2.26 The conjugate base of an acid of general formula HA is \( A^- \).

2.27 The pH of a weak acid can be calculated from the dissociation constant.

2.28 The dissociation constant of an acid can be represented by pKa where

\[ pK_a = - \log K_a \]

Indicators

2.29 Indicators are weak acids for which the dissociation can be represented as:

\[ HIn_{(aq)} + H_2O_{(l)} \rightleftharpoons H_3O^+_{(aq)} + In^-_{(aq)} \]
2.30 The acid dissociation constant is represented as $K_{\text{In}}$ and is given by the following expression

$$K_{\text{In}} = \frac{[H_3O^+][\text{In}^-]}{[\text{HIn}]}$$

2.31 In aqueous solution the colour of the acid (HIn) is distinctly different from that of its conjugate base (In$^-$).

2.32 The colour of the indicator is determined by the ratio of [HIn] to [In$^-$].

2.33 The theoretical mid-point at which colour changes occurs when

$$[H^+] = K_{\text{In}} \quad \text{or} \quad pH = pK_{\text{In}}$$

2.34 The colour change is assumed to be distinguishable when [HIn] and [In$^-$] differ by a factor of 10.

2.35 The pH range over which a colour change occurs can be estimated by the expression

$$pH = pK_{\text{In}} \pm 1$$

Buffer solutions

2.36 A buffer solution is one in which the pH remains approximately constant when small amounts of acid or base are added.

2.37 An acid buffer consists of a solution a weak acid and one of its salts.

2.38 In an acid buffer solution the weak acid can supply hydrogen ions when these are removed by the addition of a small amount of base. The salt of the weak acid provides the conjugate base, which can absorb excess hydrogen ions produced by the addition of a small amount of acid.

2.39 A basic buffer consists of a solution of a weak base and one of its salts.

2.40 In a basic buffer solution the weak base removes excess hydrogen ions and the conjugate acid provided by the salt supplies hydrogen ions when these are removed.

2.41 The pH of an acid buffer solution can be calculated from its composition and from the acid dissociation constant.

2.42 The required compositions of an acid buffer solution can be calculated from the desired pH and from the acid dissociation constant.

$$pH = pK_a - \log \left( \frac{\text{Acid}}{\text{Salt}} \right)$$
2.1 EQUILIBRIUM

Reactions at equilibrium

Introduction

Often in Chemistry, particularly when doing calculations, it is convenient to assume that reactions go to completion. This means that the reactants ultimately form the products and no reactants (unless some are present in excess) are left.

Many reactions, however, never go to completion but are in a state of equilibrium, with reactants and products always present. A chemical reaction is said to be in equilibrium when the composition of the reactants and products remains constant over time. In other words, at equilibrium the concentration of the reactants and products remains constant.

For an equilibrium to be established the reaction must take place in a closed system. A closed system is one that allows energy to be transferred to or from the surroundings but not the reactants or products. Reactants and products are trapped in the reaction vessel and reactant molecules form the products and product molecules react to reform the starting materials. The concept of a closed system can be illustrated using the following examples.

Ethanoic acid is a weak acid and shows little tendency to dissociate:

\[ \text{CH}_3\text{COOH(aq)} \rightleftharpoons \text{CH}_3\text{COO}^-(aq) + \text{H}^+(aq) \]

All the species are in solution and cannot ‘escape’, therefore this is a closed system. On the other hand, sodium carbonate reacts with dilute acid to give a salt, water and carbon dioxide, which escapes from solution and therefore this is not a closed system and equilibrium is never established. The reaction goes to completion:

\[ \text{Na}_2\text{CO}_3(aq) + 2\text{HCl(aq)} \rightarrow 2\text{NaCl(aq)} + \text{H}_2\text{O(l)} + \text{CO}_2(g) \]

If this reaction was to be carried out in a sealed container (do not attempt this in the laboratory) then equilibrium would be established since no carbon dioxide could escape:

\[ \text{Na}_2\text{CO}_3(aq) + 2\text{HCl(aq)} \rightleftharpoons 2\text{NaCl(aq)} + \text{H}_2\text{O(l)} + \text{CO}_2(g) \]

When a system is in equilibrium and the concentration of reactants and products is constant, the forward reaction (reactants to products) and the reverse reaction (products to reactants) do not stop. At equilibrium the rate of the forward reaction is equal to the rate of the reverse reaction. This means that there is no overall change in the composition of the reaction mixture when equilibrium has been established.
The equilibrium constant

Every equilibrium is described by an equilibrium constant \((K)\), which is normally measured in terms of the concentrations of the species at equilibrium but can in the case of gaseous reactions be measured in terms of pressure (more strictly by the partial pressures of the gases involved).

The same equilibrium position is always reached whether starting with the reactants or with the products at a given temperature. This means that \(K\) is independent of concentrations or pressures of the species in the equilibrium. For the general reaction:

\[
aA + bB \rightleftharpoons cC + dD
\]

\(K\) is given by the equation:

\[
K = \frac{[C]^c [D]^d}{[A]^a [B]^b}
\]

where \([\ ]\) indicates the equilibrium concentration of the species present and these concentrations are raised to the power of the number of moles of the species in the balanced equation. Equilibrium can be described as homogeneous, i.e. all the species are in one state, or heterogeneous, i.e. the species are in more than one state.

Units

Equilibrium constants have no units, they are dimensionless. The reasons for this are beyond the Advanced Higher syllabus and in fact many textbooks show no units but do not explain the reasons why. A very brief and simplistic explanation is given below.

Equilibrium constants should be calculated using activity (relative concentration) not actual concentration. Simply, the concentration terms in the equilibrium constant equation shown above should be relative concentrations, i.e. a concentration \(C\) with respect to a standard concentration \(C_0\). As both \(C\) and \(C_0\) have the same units, the units cancel out and the value obtained, the activity, has no units. Thus, using these values to calculate \(K\) means that \(K\) is dimensionless.

Pure solids and solvents

When a pure solid is present in an equilibrium reaction or a liquid is used as a solvent the concentration, at a given temperature, does not vary to a measurable extent and it is given the concentration value of 1 in the equilibrium equation. (This again comes from using activity and not
The effect of changing concentration

The effect of a change of concentration of one of the species in an equilibrium can be demonstrated using the following experiments.

(1) Dilute ethanoic acid has a pH of 3.0. When a spatula of solid sodium ethanoate is dissolved in the acid the pH rises to 3.5. This process is repeated four times and the results show that with each addition of sodium ethanoate the pH gradually increases:

$$\text{CH}_3\text{COOH}(aq) \rightleftharpoons \text{CH}_3\text{COO}^-(aq) + \text{H}^+(aq)$$
$$\text{CH}_3\text{COONa}(s) \rightarrow \text{CH}_3\text{COO}^-(aq) + \text{Na}^+(aq)$$

As the pH increases on the addition of CH$_3$COO$^-$ (aq), the concentration of H$^+$ must be falling. In other words, H$^+$ (aq) ions are reacting with the increased concentration of CH$_3$COO$^-$ (aq) ions to produce more CH$_3$COOH(aq) compared to the forward reaction. This happens because the rate of the reverse reaction increases because of the increased concentration of CH$_3$COO$^-$ (aq). This continues until the rates of the forward and reverse reactions are again equal and equilibrium is re-established. The position of the equilibrium has moved to the left, but the value of $K$ remains constant.

Overall, the increase in the concentration of CH$_3$COO$^-$ (aq) is compensated for by an increase in the concentration of CH$_3$COOH(aq) molecules and a decrease in the concentration of H$^+$ (aq) ions (therefore a rise in pH), thus keeping the value of $K$ the same:

$$K = \frac{[\text{CH}_3\text{COO}^-][\text{H}^+]}{[\text{CH}_3\text{COOH}]}$$

(2) Dilute ammonia solution has a pH of 10.0. When a spatula of solid ammonium chloride is dissolved in the acid the pH falls to 9.5. This process is repeated four times and the results show that with each addition of ammonium chloride the pH decreases:

$$\text{NH}_3(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$$
$$\text{NH}_4\text{Cl}(s) \rightarrow \text{NH}_4^+(aq) + \text{Cl}^-(aq)$$

In this case the concentration of OH$^-$ (aq) falls because of its reaction with the increased concentration of NH$_4^+$ (aq) ions to produce NH$_3$(aq) and H$_2$O(l). As before, this change occurs because the rate of the reverse reaction, compared to the forward reaction, increases because of the increased concentration of NH$_4^+$ (aq). This continues until the rates of the forward and reverse reactions are again equal and equilibrium is
re-established. The position of the equilibrium has moved to the left, but the value of $K$ remains the same.

Overall the increase in the concentration of $\text{NH}_4^+$ (aq) is compensated for by a decrease in the concentration of the $\text{OH}^-$ (aq) ion (therefore a fall in pH) and an increase in the concentration of $\text{NH}_3$(aq) and $\text{H}_2\text{O}$(l) molecules, thus keeping the value of $K$ the same:

$$K = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

(3) When dilute hydrochloric acid is added to a yellow solution of sodium chromate the solution turns orange:

$$2\text{CrO}_4^{2-}(\text{aq}) + 2\text{H}^+(\text{aq}) \rightleftharpoons \text{Cr}_2\text{O}_7^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l})$$

The added $\text{H}^+$ (aq) ions increase the rate of the forward reaction compared to the reverse reaction. This continues until the rates of the forward and reverse reactions are the same and equilibrium is re-established. The position of the equilibrium has moved to the right.

Overall the increase in the concentration of $\text{H}^+$ (aq) is compensated for by a decrease in the concentration of $\text{CrO}_4^{2-}$ (aq) ions and an increase in the concentration of $\text{Cr}_2\text{O}_7^{2-}$ (aq) ions and $\text{H}_2\text{O}$(l) molecules, thus keeping the value of $K$ the same:

$$K = \frac{[\text{Cr}_2\text{O}_7^{2-}]}{[\text{CrO}_4^{2-}][\text{H}^+]}$$
These three experiments show that changes in the concentration of one of the species in a reaction at equilibrium will bring about a shift in the equilibrium position to maintain the value of $K$ as a constant (at constant temperature).

This fact is stated formally in Le Chatelier's principle, which states that ‘when a reaction at equilibrium is subjected to change, the composition alters in such a way as to minimise the effects of the change’.

**The effect of changing temperature**

The effect of a temperature change on a reaction in equilibrium can be demonstrated in the laboratory using the following example:

$$N_2O_4 \ (g) \ \rightleftharpoons \ 2NO_2 \ (g) \ \ \Delta H = \ +ve$$

The reaction of concentrated nitric acid with copper turnings produces a mixture of $N_2O_4$ and $NO_2$. Three boiling tubes filled to an equal colour intensity with this gas mixture are collected at room temperature. One is placed in ice water (~0°C) and one in hot water (~80°C) while the third is kept, as a control, at room temperature (Figure 3). The three tubes are left for about five minutes and the colour intensities are then compared.

**Figure 3**

From the colour changes that have taken place, it is evident that the relative concentrations of $N_2O_4$ and $NO_2$ have been changed by a change in temperature. This means that the actual value of $K$ has changed. Equilibria are therefore temperature dependent. In fact most equilibrium constants are quoted at a specific temperature.
The reaction:

\[ \text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g) \quad \Delta H = +\text{ve} \]

is endothermic for the forward reaction and exothermic for the reverse. The equilibrium constant is:

\[ K = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} \]

The colour change from 20°C to 0°C shows that more \( \text{N}_2\text{O}_4 \) is formed at 0°C and therefore \([\text{N}_2\text{O}_4]\) increases and \([\text{NO}_2]\) decreases. This leads to a fall in the value of \( K \).

Similarly, the colour change from 20°C to 80°C shows that more \( \text{NO}_2 \) is formed at 80°C and therefore \([\text{NO}_2]\) increases and \([\text{N}_2\text{O}_4]\) decreases. This leads to a rise in the value of \( K \). These observations can be related to the \( \Delta H \) value and are summarised in the following way.

For endothermic reactions a rise in temperature causes an increase in \( K \) while for exothermic reactions a rise in temperature causes a decrease in \( K \).

**The effect of a catalyst**

The effect of a catalyst on an equilibrium at constant temperature is best looked at in terms of a potential energy diagram (Figure 4).

*Figure 4*
The catalyst lowers the activation energy of both the forward and reverse reactions by the same amount and there is no change in the equilibrium concentrations. The position of the equilibrium is therefore unaltered and the value of $K$ at a specific temperature remains unchanged.

All a catalyst does is to speed up the rate at which equilibrium is established.

**$K$ and the position of the equilibrium**

The value of $K$ gives an indication of how far the equilibrium lies to one side of a reaction or the other.

It is important to note that the value of $K$ gives no indication about the rate at which the state of dynamic equilibrium is established. Also, a catalyst does not increase the percentage conversion of reactants into products, it only speeds up the rate of attainment of equilibrium.

Table 1 illustrates how the value of $K$ gives an indication of the position of the equilibrium.

Equilibria involving ions

**Acid/base equilibria**

Historically acids were defined as producing hydrogen ions in solution and bases as producing hydroxide ions in solution. These two ions combine in the neutralisation equation:

\[
\text{H}^+(\text{aq}) + \text{OH}^-(\text{aq}) \rightarrow \text{H}_2\text{O(l)}
\]

As research continued throughout the nineteenth and early twentieth centuries, the definitions had to be refined. For example, pure hydrogen chloride is a gas that contains no H\(^+\) ions and ammonia has no OH\(^-\) ions but can neutralise an acid. It was also discovered that the H\(^+\) ion could not exist in aqueous solution. The H\(^+\) ion is so small (10\(^{-3}\) pm compared to other cations at 10\(^{2}\) pm) that the electric field it creates is huge and in water it attracts a lone pair of electrons to form H\(_3\)O\(^+\), which is called the hydronium ion (or the oxonium ion or the hydroxonium ion):

\[
\text{H}^+(\text{aq}) + \text{H}_2\text{O(l)} \rightarrow \text{H}_3\text{O}^+(\text{aq})
\]

The shorthand H\(^+\)(aq) is always used in stoichiometric and equilibrium equations, although this is not strictly accurate.

In 1923 the new discoveries led two chemists, Brønsted and Lowry, to define acids and bases in a different way:

*An acid is any substance capable of donating a proton.*

*An acid is any substance capable of accepting a proton.*

When an acid donates a proton the species left is called the conjugate base of that acid. When a base accepts a proton the species formed is called the conjugate acid of that base.

Table 2 gives examples of these relationships.

Table 2 also illustrates the **amphoteric** nature of water since it can act both as a proton acceptor and a proton donor.
The dissociation of water

In Brønsted–Lowry terms the ionisation of water is represented by:

\[
\begin{align*}
\text{H}_2\text{O}(l) + \text{H}_2\text{O}(l) & \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{OH}^-(aq) \\
\text{acid} & \quad \text{base} \\
\text{conjugate acid} & \quad \text{conjugate base}
\end{align*}
\]

The equilibrium constant is

\[
K = \frac{[\text{H}_3\text{O}^+][\text{OH}^-]}{[\text{H}_2\text{O}^2]}
\]

Since water is a liquid, \([\text{H}_2\text{O}] = 1\) (see page 11), giving:

\[
K = [\text{H}_3\text{O}^+][\text{OH}^-]
\]

This particular equilibrium constant is known as the ionic product \((K_w)\) for water and has the value of \(1.0 \times 10^{-14}\) at 25°C.

The water equilibrium is more usually written as:

\[
\text{H}_2\text{O}(l) \rightleftharpoons \text{H}^+(aq) + \text{OH}^- (aq) \quad K_w = [\text{H}^+][\text{OH}^-]
\]

In pure water, for every molecule which ionises, one \(\text{H}^+\) and one \(\text{OH}^-\) ion are produced, hence the \([\text{H}^+]\) in mol l\(^{-1}\) must equal the \([\text{OH}^-]\) in mol l\(^{-1}\), i.e. the number of \(\text{H}^+\) and \(\text{OH}^-\) ions in water are equal.

Substitution of \([\text{OH}^-]\) by \([\text{H}^+]\) in the above equilibrium expression gives:

\[
[\text{H}^+]^2 = 10^{-14} \text{ mol}^2 \text{ l}^{-2}
\]

taking square roots

\[
[\text{H}^+] = 10^{-7} \text{ mol l}^{-1}
\]

also

\[
[\text{OH}^-] = 10^{-7} \text{ mol l}^{-1}
\]

Note also that \([\text{H}_2\text{O}]\) in pure water = \(\frac{1000}{18}\) mol l\(^{-1}\) (neglecting the slight ionisation) = 55.5 mol l\(^{-1}\), therefore the ratio of hydrogen ions to water molecules, in water is:

\[
\frac{\text{H}^+}{\text{H}_2\text{O}} = \frac{10^{-7} \times 6.02 \times 10^{23}}{55.5 \times 6.02 \times 10^{23}} = \frac{1}{55.5} \times 10^7
\]

On average there is one \(\text{H}^+\) ion and one \(\text{OH}^-\) ion for every 555 million \(\text{H}_2\text{O}\) molecules!

\(K_w\) is always quoted as \(1.0 \times 10^{-14}\) at 25°C since the value varies with temperature:
The reaction is endothermic, an increase in temperature moves the equilibrium to the right and a decrease moves it to the left.

Table 3 shows the values of $K_w$ at different temperatures.

The pH scale

From the Higher course it will be remembered that the pH of an aqueous solution is a measure of the concentration of hydrogen ions in the solution. In fact the pH of any aqueous solution can be calculated using the expression:

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

or

$$\text{pH} = -\log[\text{H}^+]$$

The following examples illustrate its use:

pure water $[\text{H}^+] = 10^{-7}$ pH = 7
1.0 mol l$^{-1}$ HCl $[\text{H}^+] = 1.0 \times 10^0$ pH = 0
0.2 mol l$^{-1}$ HCl $[\text{H}^+] = 0.2 \times 2 \times 10^{-1}$ pH = $-\log 2 - \log (10^{-1})$

= $-0.3 + 1.0 = 0.7$

0.01 mol l$^{-1}$ NaOH $[\text{OH}^-] = 10^{-2}, [\text{H}^+] = 10^{-12}$, pH = 12
0.5 mol l$^{-1}$ NaOH $[\text{H}^+] = 2 \times 10^{-14}$ pH = $-\log 2 - \log(10^{-14})$

= $-0.3 + 14 = 13.7$

For calculations involving strong acids and alkalis it can be assumed that they are 100% dissociated and that the small number of hydrogen ions supplied by the water can be ignored.

Question

Calculate the pH of the following solutions:

(a) 0.35 mol l$^{-1}$ HNO$_3$
(b) 0.14 mol l$^{-1}$ H$_2$SO$_4$ (assume fully ionised)
(c) 0.78 mol l$^{-1}$ NaOH
The dissociation of acids

The dissociation of any acid, HA, in aqueous solution can be represented by the equation:

\[
\text{HA}(\text{aq}) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{A}^-(\text{aq})
\]

The dissociation constant of acid HA from the above equation is:

\[
K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}
\]

and is a measure of the strength of the acid.

The [H\textsubscript{2}O] has been omitted as it is the solvent and taken to be 1.

In strong acids the above equilibrium lies to the right with effectively complete dissociation so that \(K_a\) has no meaning. However, some acids do not dissociate well (less than 5\%) in aqueous solution and these are called weak acids.

Conveniently, nearly all acids fall into one of these two categories. Within the weak acids, the value of \(K_a\) gives a measure of how weak (or how dissociated) the acid is: the smaller the value of \(K_a\), the weaker the acid.

Calculation of pH of a weak monobasic acid

Using the dissociation constant from the previous page, the pH of a weak monobasic acid can be calculated.

\[
K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}
\]

Since \([\text{H}_3\text{O}^+] = [\text{A}^-]\)

\[
K_a = \frac{[\text{H}_3\text{O}^+]}{[\text{HA}]}
\]

Taking logs of both sides:

\[
\log K_a = \log[H_3O^+] - \log[HA]
\]

= \(2\log[H_3O^+] - \log[HA]\)
but \(-\log[H_3O^+] = \text{pH}\), and assigning \(-\log K_a\) as \(pK_a\) we get:

\[
\begin{align*}
-pK_a & = -2\text{pH} - \log[HA] \\
pK_a & = 2\text{pH} + \log[HA]
\end{align*}
\]

For a weak acid HA of concentration \(c\) mol l\(^{-1}\), [HA] at equilibrium will be approximately equal to the original concentration \(c\) mol l\(^{-1}\), so:

\[
pK_a = 2\text{pH} + \log c
\]

which can be rearranged to give the expression:

\[
\text{pH} = \frac{1}{2}pK_a - \frac{1}{2}\log c
\]

This equation is only valid for weak acids in which the concentration of HA at equilibrium is almost the same as the original concentration.

The weaker the acid is, the more closely the calculated pH will approach the actual pH of the solution. The stronger the acid, the more inaccurate the calculated pH will be.

### Questions

1. Calculate the pH of a 0.2 mol l\(^{-1}\) solution of ethanoic acid if \(K_a = 1.7 \times 10^{-5}\).

2. 0.02 mol l\(^{-1}\) benzoic acid \(C_6H_5COOH\), a monobasic acid, was found to have a pH of 2.94. Calculate the \(K_a\) of this weak acid.

### Indicators

Indicators are used to determine the end-point in an acid–alkali titration. A suitable indicator must be chosen for any given reaction. Indicators are dyes whose colours are sensitive to pH. An indicator is usually a weak acid that dissociates as shown:

\[
\text{HIn(aq)} + \text{H}_2\text{O(l)} \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{In}^- (aq)
\]

The unionised form of the indicator (HIn) has a different colour from its conjugate base (In\(^-\)). The equilibrium constant (\(K_{\text{in}}\)) for the above equation is:

\[
K_{\text{in}} = \frac{[\text{H}_3\text{O}^+][\text{In}^-]}{[\text{HIn}]}
\]

Rearranging this expression gives:
This shows that the relative concentrations of the two coloured forms is a function of the $H_3O^+$ concentration, i.e. the pH of the solution. It follows therefore that the colour of the indicator in any given solution depends on the relative concentrations of the two coloured forms, which in turn is determined by the pH. The theoretical point at which the colour change occurs is when $[HIn] = [In^-]$ and therefore $K_{In} = [H_3O^+]$. In other words, the colour change occurs when $pK_{In} = pH$. In practice the colour change cannot be seen when $[HIn] = [In^-]$ and it is only distinguishable when $[HIn]$ and $[In^-]$ differ by a factor of 10.

The pH range over which a colour change can be seen is therefore established using the expression:

$$pH = pK_{In} \pm 1 \quad \text{(log 10 = 1)}$$

The appropriate indicator for any titration must be chosen such that the colour change occurs over the pH range when the pH is changing very rapidly. This means that the indicator must change colour during the addition of, say, half a drop of reagent. The indicator for a reaction can therefore be chosen by reference to titration curves, which are drawn from data obtained by measuring the pH of an acid continuously against the volume of alkali added during and after neutralisation (Figures 9–12).

Consider the titration of a strong acid with a strong alkali (Figure 9), e.g. the addition of 0.01 mol l\(^{-1}\) NaOH solution to 50 cm\(^3\) of 0.01 mol l\(^{-1}\) HCl. The pH of the original acid solution will be 2 ($[H^+] = 10^{-2}$ mol l\(^{-1}\)). When 49 cm\(^3\) of NaOH solution has been added there will be only 1 cm\(^3\) of the original 0.01 mol l\(^{-1}\) HCl left un-neutralised. This amount is now in an overall volume of $50 + 49$ cm\(^3\) $\sim 100$ cm\(^3\), i.e. the solution is now 0.0001 mol l\(^{-1}\) with respect to H\(^+\)(aq), thus $[H^+] = 10^{-4}$ mol l\(^{-1}\) and pH = 4.

*Figure 9*
On adding 49.9 cm$^3$ alkali, only 0.1 cm$^3$ of acid will remain in ~100 cm$^3$ solution and therefore [H$^+$] = 10$^{-5}$ mol l$^{-1}$ and pH = 5. When 49.99 cm$^3$ alkali has been added the pH of the solution is 6 and at 50 cm$^3$ the pH rises to 7 and neutralisation is complete.

Note the rapid rise in pH as the end-point of the titration is approached. Thereafter the alkali added has nothing to react with and the pH continues to rise to a final value of 12.

The titration curves in Figures 10 and 11 show the pH changes that occur on titrating weak and strong alkalis (50 cm$^3$) with equimolar solutions of strong and weak acids (50 cm$^3$) respectively.

**Figure 10**

**Figure 11**
It can be seen from Figures 9, 10 and 11 that there is a region of rapid pH change around the end-point. For an indicator to be suitable, its pH range must fall within this region. From Figure 9 it can be seen that for a strong acid and strong alkali a suitable indicator can have a colour change within the pH range 3–10. From Figure 10 an indicator for a strong acid and weak alkali would change somewhere in the range 3–7. Similarly, from Figure 11, for a weak acid and strong alkali, a suitable indicator must change colour within the pH range 7–10.

It is not possible to select any suitable indicator for a weak acid/weak alkali combination (Figure 12), since the pH does not change rapidly enough at the end-point, i.e. the titration curve does not have an almost vertical section like the others.

**Figure 12**

![Titration curve](image)

Table 4 shows some common indicators, their pH range and colours.

**Question**
From Table 4 above, calculate the $pK_a$ and $K_a$ for the four indicators.

**Buffer solutions**

A buffer solution is one in which the pH of the solution remains approximately constant when small amounts of acid or base are added or the solution is diluted with water.

An **acidic buffer** consists of a solution of a weak acid and one of its salts with a strong alkali. A **basic buffer** consists of a solution of a weak base and one of its salts with a strong acid.

Both types of buffer solution work in the same way.

In an acid buffer solution, the weak acid supplies more hydrogen ions when the existing ones are removed by a base being added, while the salt of the weak acid provides the conjugate base to react with the hydrogen ions when small amounts of acid are added.

In a basic buffer solution, the weak base reacts with the hydrogen ions when acid is added and the salt provides the conjugate acid, which dissociates to replace the hydrogen ions when these are removed by addition of small amounts of base.

In consequence, the pH hardly changes in both cases.

This principle is illustrated by an acid buffer of weak acid HA and the sodium salt of that acid NaA. In solution the following occurs:

\[
\text{HA(aq)} + \text{H}_2\text{O(l)} \rightleftharpoons \text{H}_3\text{O}^+\text{(aq)} + \text{A}^-\text{(aq)} \quad \text{equilibrium}
\]

and

\[
\text{NaA(aq)} \rightarrow \text{Na}^+\text{(aq)} + \text{A}^-\text{(aq)} \quad \text{fully ionised}
\]

NaA is fully ionised in solution and therefore the $[A^-]$ is very large, forcing the equilibrium to the left.

Addition of small volumes of $\text{H}^+$ does not alter the pH greatly since an increase in $[\text{H}^+]$ favours the reverse reaction (HA formation) to maintain $K_a$. Since $[A^-]$ is high compared to $[\text{H}^+]$ in the original buffer solution, its ability to remove $\text{H}^+$ ions is substantial (but not infinite) and the pH of the solution is maintained.

In the same way, addition of $\text{OH}^-$ does not alter the pH greatly since the $\text{OH}^-$ ions combine with the $\text{H}^+$ of the weak acid until $K_w$ is attained. Removal of $\text{H}^+$ means that more HA ionises, giving $\text{H}^+ + \text{A}^-$ until equilibrium is re-established, and the pH of the solution is maintained:
$K_a = \frac{[H_3O^+][A^-]}{[HA]}$

$[H_3O^+] = K_a \frac{[HA]}{[A^-]}$

where $[HA]$ is the concentration of the acid as it is a weak acid and $[A^-]$ is the concentration of the salt as it is fully ionised and very little comes from the acid dissociating. Therefore:

$[H_3O^+] = K_a \frac{[\text{acid}]}{[\text{salt}]}$

If the buffer solution has water added to it, i.e. it is diluted, both $[\text{acid}]$ and $[\text{salt}]$ are equally affected and therefore $[H_3O^+]$ and the pH remain unaltered.

An efficient buffer must have a reasonable reserve of HA and A⁻ as the H⁺ from HA removes added OH⁻ and the A⁻ removes added H⁺, therefore since:

$[H_3O^+] = K_a \frac{[\text{acid}]}{[\text{salt}]}$

if $[\text{acid}] = [\text{salt}]$ the buffer will have the same ability to resist addition of H⁺ and OH⁻.

Similar reasoning can be used to show how a basic buffer solution operates.

The pH of an acid buffer solution can be calculated by conversion of the above equation:

$[H_3O^+] = K_a \frac{[\text{acid}]}{[\text{salt}]}$

to $\text{pH} = pK_a - \log \frac{[\text{acid}]}{[\text{salt}]}$

**Questions**

1. Calculate the pH of the buffer solution made from 1.0 mol l⁻¹ methanoic acid and 1.78 mol l⁻¹ sodium methanoate solution. The $pK_a$ of methanoic acid is 3.8.

2. Calculate the pH of the buffer solution made from 0.1 mol l⁻¹ solution of ethanoic acid and potassium ethanoate. The $pK_a$ of ethanoic acid is 4.8.
The composition of an acid buffer solution can be calculated from the same 
equation as long as the required pH and the pK$_a$ of the acid are known, e.g. to 
make an acidic buffer of pH 5.0, using propanoic acid pK$_a$ 4.9.

\[
\text{pH} = \text{pK}_a - \log \frac{[\text{acid}]}{[\text{salt}]}
\]

\[
5.0 = 4.9 - \log \frac{[\text{acid}]}{[\text{salt}]}
\]

\[
\log \frac{[\text{acid}]}{[\text{salt}]} = -0.1
\]

\[
\log \frac{[\text{salt}]}{[\text{acid}]} = 0.1
\]

\[
\frac{[\text{salt}]}{[\text{acid}]} = 1.26, \text{ which is a ratio of } \frac{1.26}{1}
\]

The buffer is therefore made by mixing 1.26 moles of sodium propanoate 
with 1.0 mole of propanoic acid per litre of solution required.

**Question**

Calculate the concentrations of acid and salt solutions required to make:

(a) a buffer of pH 6.0 from carbonic acid and sodium hydrogen carbonate 
(pK$_a$ of carbonic acid is 6.4)

(b) a buffer of pH 3.1 from chloroethanoic acid and its potassium salt (pK$_a$ 
of chloroethanoic acid is 2.9).

Buffer solutions are important in biological systems, especially those where 
enzymes work within narrow pH ranges, e.g. blood is a buffered solution of 
pH around 7.4 (CO$_2$/bicarbonate equilibrium is maintained by respiration and 
excretion of bicarbonate into the urine).

The sea is also a buffer because it contains significant concentrations of 
carbonate and hydrogencarbonate ions. These act as a buffer, maintaining the 
PpH of the sea within certain limits, and this allows marine life to exist:

\[
\text{H}_2\text{CO}_3 \rightleftharpoons H^+ + \text{HCO}_3^- \rightleftharpoons 2H^+ + \text{CO}_3^{2-}
\]
Phosphate solutions can act as buffers because the second and third dissociations of phosphoric acid are weak:

\[
\begin{align*}
H_3PO_4 & \rightarrow H^+ + H_2PO_4^- \\
H_2PO_4^- & \rightleftharpoons H^+ + HPO_4^{2-} \\
HPO_4^{2-} & \rightleftharpoons H^+ + PO_4^{3-}
\end{align*}
\]

Another useful buffer in the laboratory is potassium hydrogenphthalate, which is a weak acid and its salt all in one molecule:
Q1  The value for the equilibrium constant, $K$, for a specific example of the following reaction is equal to 1:

\[
\text{acid} + \text{alcohol} \rightleftharpoons \text{ester} + \text{water}
\]

a)  i)  Predict the maximum yield of ester, given this value of $K$.  

ii)  Give one reason why this yield might not be achieved in practice.

b)  A student suggested that a careful choice of catalyst could increase the yield of ester. Comment on this suggestion.

b)  Another student suggested that increasing the concentration of the alcohol in the reaction mixture would increase the yield of ester by altering the value of $K$. Comment on this suggestion.

Q2  The balanced equation for the principle reaction in the contact process is:

\[
2\text{SO}_{2(g)} + \text{O}_{2(g)} \rightleftharpoons 2\text{SO}_{3(g)} \quad \Delta H = -\text{ve}
\]

a)  Write an expression for $K$, the equilibrium constant for this reaction, when the system has reached equilibrium.

b)  i)  State Le Chatelier’s Principle.

ii)  Use this generalisation to predict how an increase in temperature would affect the position of equilibrium.

iii)  Explain the effect this increase in temperature would have on the value of $K$.

Q3  Write the formula for the conjugate base of each of the following acids:

a)  $\text{H}_3\text{O}^+$

b)  $\text{H}_2\text{O}$

c)  $\text{NH}_4^+$

KHS Chemistry Feb 2014  
Equilibria
In the Data Booklet, the solubility of barium sulphate, shown by the equation:

\[
\text{BaSO}_4(s) + \text{water} \rightleftharpoons \text{Ba}^{2+}_{(aq)} + \text{SO}_4^{2-}_{(aq)}
\]
is given as less than 1 g l\(^{-1}\). In a more advanced text book, it is noticed that an equilibrium constant, known as the solubility product \(K_{sp}\), can be written to represent the dissolving process. \(K_{sp}\) is equal to the product of the concentrations of the ions in the solution:

\[
K_{sp} = [\text{Ba}^{2+}] \times [\text{SO}_4^{2-}]
\]

\(a\) At 298K, \(K_{sp}\) for barium sulphate is equal to \(1 \times 10^{-10}\) mol\(^2\) l\(^{-2}\)

For a saturated solution of barium sulphate at 298K, calculate

\(i\) the concentration of barium ions dissolved in the solution. 1

\(ii\) the mass of barium sulphate dissolved in 1 litre of solution. 3

\(b\) A small quantity of very soluble sodium sulphate is now added to the saturated solution of barium sulphate.

\(i\) What will happen to the value of \(K_{sp}\)? 1

\(ii\) What will happen to the concentration of barium ions? 1

\(Q5\) Substance X is distributed between equal volumes of two immiscible liquids as shown in the diagram. The number of dots represents the relative distribution of X in the two liquids at equilibrium.

The value of the equilibrium constant for this system is

\[
\begin{align*}
A & \quad 0.46 \\
B & \quad 0.50 \\
C & \quad 2.00 \\
D & \quad 2.17.
\end{align*}
\]
Q6  a) Calculate the pH of a solution of ethanoic acid with a concentration of 0.01 mol l\(^{-1}\). \((K_a\) ethanoic acid = \(1.7 \times 10^{-5}\)).

\[
\text{b) A mixture of ethanoic acid and sodium ethanoate solution constitutes a buffer solution. Show how this buffer solution is able to resist change in pH when small quantities of each of the following are added.}
\]

i) hydrochloric acid

ii) sodium hydroxide solution

\[
\text{c) The simplified equation for the pH of a buffer solution is:}
\]

\[
\text{pH} = \text{pK}_a - \log \left( \frac{[\text{acid}]}{[\text{salt}]} \right)
\]

A buffer solution was prepared from ethanoic acid (0.25 mol l\(^{-1}\)) and sodium ethanoate solution (0.15 mol l\(^{-1}\)).

Calculate the pH of the buffer solution.

\[
\text{SYS 94 (9)}
\]

Q7  Propanoic acid is a weak acid. Sodium propanoate is a salt which can be formed from it. Both propanoic acid and sodium propanoate can be used as mould inhibitors.

\[
\text{a) Calculate the pH of 0.10 mol l\(^{-1}\) propanoic acid solution.}
\]

\[
\text{b) 0.20 moles of sodium propanoate are added to 100 cm}^3\ \text{of the 0.10 mol l}^{-1}\ \text{solution of propanoic acid.}
\]

Calculate the pH of the buffer solution formed.

\[
\text{RevAdV 13 (4)}
\]

Q8  The salt sodium propanoate, \(\text{C}_2\text{H}_5\text{COO}^-\text{Na}^+\), is produced when sodium hydroxide reacts with propanoic acid. When sodium propanoate is dissolved in water an alkaline solution is formed.

\[
\text{a) i) Write the formula for the conjugate base of propanoic acid.}
\]

\[
\text{ii) Explain why a solution of sodium propanoate is alkaline.}
\]
The titration of propanoic acid with sodium hydroxide can be followed using a pH meter.

The graph below was obtained when 40.0 cm$^3$ of an aqueous solution of propanoic acid was titrated with 0.200 mol l$^{-1}$ sodium hydroxide.

\[ \text{Volume of 0.200 mol l}^{-1} \text{ sodium hydroxide solution/cm}^3 \]

\[ \text{pH} \]

\[ i) \] The initial pH was recorded as 2.93. Calculate the initial concentration of the propanoic acid.

\[ ii) \] The table shows four indicators which could be used to detect the end-point of a titration.

<table>
<thead>
<tr>
<th>Indicator</th>
<th>pH range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phenolphthalein</td>
<td>8.3 – 10.0</td>
</tr>
<tr>
<td>Bromophenol red</td>
<td>5.2 – 6.8</td>
</tr>
<tr>
<td>Methyl orange</td>
<td>3.1 – 4.4</td>
</tr>
<tr>
<td>Methyl red</td>
<td>4.2 – 6.3</td>
</tr>
</tbody>
</table>

Why is phenolphthalein the most suitable indicator for this titration?

\[ c) \] Phenolphthalein is a weak acid. The equation shows how phenolphthalein dissociates.

\[ \text{[Phenolphthalein]} \rightleftharpoons \text{[Phenolphthalein$^-$] + 2H$^+$} \]

With reference to the above equilibrium, explain why the colour changes from colourless to pink at the end-point.
Q9  The ionic product of water \((K_w)\) is usually taken to be \(10^{-14}\), but it varies with temperature. The following table shows this variation.

<table>
<thead>
<tr>
<th>Temperature / K</th>
<th>(K_w)</th>
</tr>
</thead>
<tbody>
<tr>
<td>273</td>
<td>(0.114 \times 10^{-14})</td>
</tr>
<tr>
<td>283</td>
<td>(0.293 \times 10^{-14})</td>
</tr>
<tr>
<td>298</td>
<td>(1.008 \times 10^{-14})</td>
</tr>
<tr>
<td>323</td>
<td>(5.476 \times 10^{-14})</td>
</tr>
<tr>
<td>373</td>
<td>(51.3 \times 10^{-14})</td>
</tr>
</tbody>
</table>

\(a\)  What is meant by the term ‘ionic product of water’?

\(b\)  Since \(K_w\) varies with temperature, the pH of pure water is not always 7. Calculate the pH of pure water at 373K.

\(c\)  The ionisation of water is endothermic. Explain how the information in the table supports this statement.

SYS 91 (5)

Q10  Phosphoric(V) acid, \(H_3PO_4\), is triprotic. When neutralised by sodium hydroxide solution, it can form three different salts.

\(a\)  Give the formula for each of the three sodium salts of the acid.

\(b\)  The first stage of the ionisation of phosphoric (V) acid has a dissociation constant of \(7.08 \times 10^{-3}\).

Calculate the approximate pH of a 0.1 mol \(\text{l}^{-1}\) solution of phosphoric(V) acid. (You can assume that the other two stages in the ionisation do not significantly affect the hydrogen ion concentration).

SYS 91 (5)

Q11  Limewater is a saturated solution of calcium hydroxide. At 20°C, 100 cm\(^3\) of a limewater solution contained 0.126g of calcium hydroxide.

\(a\)  Calculate the concentration of hydroxide ions, in mol \(\text{l}^{-1}\), in this solution.

\(b\)  Using your answer to part \(a\), calculate the pH of the solution

SYS 99 (4)
Q12  At 298K the dissociation constant $K_w$ for water is $1 \times 10^{-14}$. The graph shows the variation of $K_w$ with temperature.

From the graph calculate the pH of water at 288K.

Q13  Most Indicators are weak acids of general formula HIn. Their dissociation in aqueous solution can be represented as:

$$\text{HIn} \rightleftharpoons \text{H}^+ + \text{In}^-$$

colour A \hspace{1cm} \text{colour B}

$$K_{\text{indicator}} = \frac{[\text{H}^+][\text{In}^-]}{[\text{HIn}]}$$

At the end point, $[\text{In}^-] = [\text{HIn}]$ and therefore $K_{\text{indicator}} = [\text{H}^+]$.

Use the above and the information in the table below to answer the questions that follow.

<table>
<thead>
<tr>
<th>Indicator</th>
<th>$K_{\text{indicator}}$</th>
<th>Colour change (low pH → high pH)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methyl yellow</td>
<td>$5.1 \times 10^{-4}$</td>
<td>red → yellow</td>
</tr>
<tr>
<td>Bromothymol blue</td>
<td>$1.0 \times 10^{-7}$</td>
<td>yellow → blue</td>
</tr>
<tr>
<td>Thymol Blue</td>

</tbody>
</table>
Q13 contd

a) At what pH would the colour change be expected to take place in each of the indicators?  

b) A student is asked to carry out a titration of ethanoic acid and sodium hydroxide. Which indicator in the table is most suitable for the titration? Give a reason for your choice.  

SYS 95 (4)

Q14 250 cm$^3$ of sulphurous acid solution was prepared by dissolving 1.6g of sulphur dioxide in water at 298K.

a) Calculate the concentration of the acid in mol l$^{-1}$.  

b) Using your answer to a) and your Data Booklet, calculate the pH of the acid solution.  

c) Why is this acid unsuitable for use as a primary standard?  

d) If this acid is standardised using a strong alkali, what will be the approximate pH range of the indicator needed for the titration?  

SYS 98 (7)
Answers

Q1  a) i) Yield = 50%  
      ii) side reactions or impurities

b) The suggestion is wrong. 
   A catalyst only brings the reaction to the same equilibrium more quickly.

c) K is a constant at a fixed temperature and altering the alcohol concentration will not change the value of K. It will, however, increase the yield of the ester as the forward reaction will be increased.

Q2  a) K = [SO₃]/[SO₂]²[O₂]

b) i) Le Chatelier’s principle states that if a system is subjected to any change, the system readjusts itself to counteract the applied change.

ii) Increased temperature favours ΔH +ve. Thus the backward reaction is favoured and the equilibrium position moves to the left.

iii) K will decrease.

Q3  a) H₂O

b) OH⁻

c) NH₃
Q4  

**a)** \([\text{Ba}^{2+}] = \sqrt{1 \times 10^{-10}} = 1 \times 10^{-5} \text{ mol l}^{-1}\) 

**b)** \(\text{BaSO}_4 = 233.4 \text{ g mol}^{-1}\)

Mass dissolving \(= 233.4 \times 1 \times 10^{-5}\) 
\(= 2.334 \times 10^{-3} \text{ g}\)

**c)**  

i) \(K_{sp}\) is a constant therefore stays the same.

ii) The equilibrium moves to the left therefore \([\text{Ba}^{2+}]\) decreases.

Q5  

**D**

Q6  

**a)** \(\text{pH} = \frac{1}{2} pK_a - \frac{1}{2} \log c\)

\(= \frac{1}{2} \times 4.77 - \frac{1}{2} \log 0.01\)
\(= 2.385 - (-1)\)
\(= 3.4\)

or \(K_a = \frac{[\text{H}^+]^2}{[\text{CH}_3\text{COOH}]}\)

Therefore \([\text{H}^+] = \sqrt{(1.75 \times 10^{-5} \times 0.01)}\)
\(= \sqrt{1.7} \times 10^{-7}\)
\(= 4.12 \times 10^{-4}\)

\(\text{pH} = -\log [\text{H}^+] = -\log 4.12 \times 10^{-4} = 3.4\)

**b)** \(\text{CH}_3\text{COOH}_\text{(aq)} \rightleftharpoons \text{CH}_3\text{COO}^-\text{(aq)} + \text{H}^\text{(aq)}\)

\(\text{CH}_3\text{COO}^-\text{Na}^\text{(s)} \rightarrow \text{CH}_3\text{COO}^-\text{(aq)} + \text{Na}^\text{+(aq)}\)

i) Add HCl – the \(\text{H}^\text{+(aq)}\) ions added react with the excess \(\text{CH}_3\text{COO}^-\text{(aq)}\) from the salt.

ii) Add NaOH – the \(\text{OH}^-\text{(aq)}\) added reacts with the \(\text{H}^\text{+(aq)}\) from the acid and more \(\text{CH}_3\text{COOH}\) ionises to replace the \(\text{H}^\text{+(aq)}\) ions removed.

**c)** \(\text{pH} = pK_a - \log[\text{acid}]/[\text{salt}] = 4.77 - \log 0.25/0.15\)
\(= 4.55\)
Q7  a) \[ \text{pH} = \frac{1}{2} \text{pKa} - \frac{1}{2} \log c \quad (1) \]
\[ = 2.935 \text{ or } 2.94 \text{ or } 2.9 \quad (1) \]

b) \[ \text{pH} = \text{pKa} - \log [\text{acid}] \frac{[\text{salt}]}{[\text{salt}]} \quad (1) \]
\[ = 6.171 \text{ or } 6.17 \text{ or } 6.21 \quad (1) \]

(2)

Q8  a) i) \[ \text{C}_2\text{H}_5\text{COO}^- \text{ (aq)} \text{ or CH}_3\text{CH}_2\text{COO}^- \text{ (aq)} \text{ or C}_3\text{H}_5\text{O}_2^- \text{ (aq)} \]
(aq) can be omitted  

ii) Conjugate base removes hydrogen ions \ 
Water equilibrium shifts right and hydroxide ions are in excess \ 
(Could also use equations to explain.)  

b) i) \[ \text{pH} = \frac{1}{2} \text{pKa} - \frac{1}{2} \log c \quad (1) \]
\[ 2.93 = \frac{1}{2} (4.87) - \frac{1}{2} \log c \quad (1) \]
\[ c = 0.1 \text{ mol l}^{-1} \quad \text{(lose mark if no unit)} \quad (1) \]

ii) pH range is best match for equivalence point or end-point or pH range of phenolphthalein fits into “vertical” part of graph  

(4)

Q9  a) The product of \([\text{H}^+ \text{ (aq)}] \times [\text{OH}^- \text{ (aq)}]\)  

b) \[ [\text{H}^+]^2 = 51.3 \times 10^{-14}, \quad (1) \]
therefore \([\text{H}^+] = 7.16 \times 10^{-7} \text{ and } \quad (1) \]
\[ \text{pH} = 6.15 \quad (1) \]

(3)

c) An increase in temperature favours \(\Delta H +\text{ve.} \) As the temperature increases so does the value of \(K_w\) and therefore more ions form. Thus the ionisation is endothermic.
**Q10**

**a)** NaH$_2$PO$_4$, Na$_2$HPO$_4$, Na$_3$PO$_4$ (any two, 1+1)

**b)**

$$K_a = [H^+][H_2PO_4^-]/[H_3PO_4]$$  

$$7.08 \times 10^{-3} = [H^+]^2/0.1$$

$$[H^+]^2 = 7.08 \times 10^{-4}$$

$$[H^+] = 2.66 \times 10^{-2}$$  

$$\text{pH} = 1.6$$  

(You could also use $\text{pH} = \frac{1}{2}pK_a - \frac{1}{2}\log[C]$.)

**Q11**

**a)**

$$[\text{Ca(OH)}_2] = \frac{0.126}{74} \text{ moles per 100 cm}^3$$

$$= 0.017 \text{ mol l}^{-1}$$  

$$[\text{OH}^-] = 2 \times 0.017 = 0.034 \text{ mol l}^{-1}$$  

**b)**

$$[H^+] = 10^{-14}/0.034 = 2.94 \times 10^{-13}$$

$$\text{pH} = -\log(2.94 \times 10^{-13}) = 12.53$$

**Q12**

$$K_w \text{ at 288K} = 0.45 \times 10^{-14}$$

$$[H^+] = 6.71 \times 10^{-8}$$

$$\text{pH} = -\log(6.71 \times 10^{-8}) = 7.17$$

**Q13**

**a)**

Methyl yellow  $\text{pH} = 3.3$

bromothymol blue  $\text{pH} = 7$

thymol blue  $\text{pH} = 8.9$  (3 correct = 2; 1 or 2 correct = 1)

**b)**

Thymol blue.

The titration involves a weak acid and strong alkali therefore the salt will have a pH above 7.  

(1)  

(4)
**Q14 a)** \( \frac{1.6}{64.1} = 0.025 \text{ mol in 250 cm}^3 \) \( = 0.1 \text{ mol l}^{-1} \)

**b)** \( \text{pH} = \frac{1}{2} \text{pKa} - \frac{1}{2} \log c \)
\( = (\frac{1}{2} \times 1.8) - (\frac{1}{2} \log 0.1) \)
\( = 1.4 \)

or \( K_a = \frac{[H^+][HSO_3^-]}{[H_2SO_4]} \)
\( H^+ = \sqrt{K_a \times [H_2SO_4]} = \sqrt{(1.5 \times 10^{-2}) \times 0.1} \)
\( = 3.87 \times 10^{-2} \)
\( \text{pH} = - \log [H^+] = 1.4 \)

(If the wrong equation is used then zero marks.)

**c)** It is volatile, i.e. SO\(_2\) is given off from solution.

or It is unstable.

**d)** Accept range within 7.5 – 10.5 but must have at least 1.5 of a difference between values.
