**End-of-Topic Assessment**

Score: %

Grade:
4.1 Acids & Bases

Common Acids

Acids are all around you. Most are safe to handle but some are definitely not.

Fizz drinks (CO$_2$, carbonic acid), some fruits like lemon and orange (citric acid), vinegar and ketchup (ethanoic acid), and even many vegetables (ascorbic acid, vitamin C) contain acid. These are examples of weak acids. A more unpleasant example is a bee sting, nettle sting or ant bite (formic acid).

Stronger acids are found in car bat (sulfuric acid) while our stomach contain acid (hydrochloric) to break down our food into smaller molecules.

- Acids taste sour - the Latin word for sour was “acidus”
- Acids kill cells - the most vulnerable part of you is your eye, because they have living cells on the surface (Safety Glasses!)
- Acids react with iron objects, like the Forth Rail Bridge, rust much faster these days because of acid rain.
- Acids react with carbonates - acid rain is destroying many of the marble statues in the world
- Acids react with alkalis - the leaves of a dock (or docken) plant can neutralise the sting from a nettle
- Acids change the colour of indicators - e.g. they turn universal indicator from green to red
- Acids have a pH less than 7 - on a pH scale that goes from to .
**Bases** are also all around you. *Most are safe to handle but some are definitely not.*

*Toothpaste* contains a **base** to help neutralise the *acid* on your *tee*, produced by *bacteria*. Most *soap* and *detergent* contain bases to help cope with *grease* and *oil* stains. Our *liver* produces *bile* (a *base*) to help break down *fat* foods. *Farmers* and *gardeners* will spread *lime* (*calcium hydroxide*) on the soil if it is too *acidic*.

*Wasp* stings are basic, and just as painful as any acid. Other harmful **bases** are found in *bleach* (*ammonia*).

- **Bases feel slippery** - most *soap* are basic
- **Bases kill cells** - the most vulnerable part of you is your *eye*, because they have *liver* cells on the *surface* (Safety Glasses!)
- **Bases react with acids** - *wasp* stings (alkali) should be treated with an acid like *vinegar* or *lemon* juice, while *bee* stings need *baking soda* (a base).

*Acid* fumes (*SO₂* and *CO₂*) from *coal* burning *power stations* are passed through *lime* to be neutralised.

The *human* stomach produces *hydrochloric acid* to help the *enzyme* (*catalyst*) *pepsin* to break down *protein*. Sometimes too much *acid* is made and it begins to attack the stomach *wall* causing *pain*. All stomach remedies contain **bases** to neutralise the stomach acid.

- **Bases change the colour of indicators** - e.g. they turn *universal indicator* from *green* to *purple"
- **Bases have a pH greater than 7** - on a pH scale that goes from 0 to 14.
Our main source of bases are the **Metal Oxides**.

e.g., lime & calcium oxide  
soda & sodium oxide  
magnesia & magnesium oxide  
pearl ash & potassium oxide

Though, we also use many **Metal Carbonates**.

e.g., limestone & calcium carbonate  
marble & calcium carbonate  
baking soda & sodium carbonate  
potash & potassium carbonate

**Bases are mainly metal oxides and metal carbonates**

All of these bases are ionic compounds and, therefore, solids at room temperature. As solids, they can be directly added to an acid and will neutralise the acid.

\[
\text{base} + \text{acid} \rightarrow \text{salt} + \text{water}
\]

Sometimes, however we prefer to use sol of soluble bases which we then can call alk.

Most alk are made by dis a me oxide in wa - though only those in Group 1 are very sol. (Data Booklet)

\[
\text{soda (s)} + \text{H}_2\text{O (l)} \rightarrow \text{NaOH (aq)} \quad \text{sodium hydroxide}
\]
\[
\text{K}_2\text{O (s)} + \text{H}_2\text{O (l)} \rightarrow \text{KOHH (aq)} \quad \text{potassium hydroxide}
\]
\[
\text{CaO (s)} + \text{H}_2\text{O (l)} \rightarrow \text{Ca(OH)2 (aq)} \quad \text{calcium hydroxide}
\]
\[
\text{magnesia (s)} + \text{H}_2\text{O (l)} \rightarrow \text{Mg(OH)2 (aq)} \quad \text{magnesium hydroxide}
\]

**The soluble metal oxides can form alkanis with water**
Making Acids

Probably one of the first times the word *ac* was met was in the phrase “ac ra”.

**Ga** like *nitr* *dioxide*, NO₂, (produced in *pet* engines) and *sul* *dioxide*, SO₂, (co burning *pow* stations) both dissolve to produce *ac solu*.

\[ \text{SO}_2 (g) + \text{H}_2\text{O} (l) \rightarrow \text{H}_2\text{SO}_3 (aq) \]

**Fiz** drinks are *ac* because *car* *dioxide*, CO₂, dissolves to form *carb* acid, H₂CO₃.

Other *n -met oxi* like SO₃ (*sulf* acid, H₂SO₄) and P₂O₅ (*phosph* acid) behave this way, though *insol oxi* like carbon *mo* *ide*, CO, cannot form *ac* solutions.

**The soluble non-metal oxides can form acids with water**

\[
\begin{align*}
\text{SO}_2 (g) + \text{H}_2\text{O} (l) & \rightarrow \text{H}_2\text{SO}_3 (aq) \\
\text{H}_2\text{O} (l) + \text{SO}_3 (g) & \rightarrow \text{H}_2\text{SO}_4 (aq) \\
\text{CO}_2 (g) + \text{H}_2\text{O} (l) & \rightarrow \text{H}_2\text{CO}_3 (aq) \\
\text{NO}_2 (g) + \text{H}_2\text{O} (l) + \text{O}_2 (g) & \rightarrow \text{HNO}_3 (aq) \\
\text{P}_2\text{O}_5 (s) + \text{H}_2\text{O} (l) & \rightarrow \text{H}_3\text{PO}_4 (aq)
\end{align*}
\]

Not all of our acids are made from oxides, however.

\[
\begin{align*}
\text{H}_2\text{O} (l) + \text{H}_2\text{S} (s) & \rightarrow \text{H}_2\text{S} (aq) \\
\text{H}_2\text{O} (l) + \text{H}_2\text{S} (g) & \rightarrow \text{H}_2\text{S} (aq)
\end{align*}
\]

\[ \text{H}_2\text{S} (aq) \rightarrow \text{H}_2\text{S} (aq) \]

\[ \text{H}_2\text{S} (aq) \rightarrow \text{H}_2\text{S} (aq) \]

\[ \text{H}_2\text{S} (aq) \rightarrow \text{H}_2\text{S} (aq) \]

\[ \text{H}_2\text{S} (aq) \rightarrow \text{H}_2\text{S} (aq) \]
Q1. Acids and Bases are found everywhere around us. For each of the substances listed below, decide whether they are acids (A) or bases (B).

lemon juice  toothpaste  lime
wasp stings  vitamin C  Coca Cola
tomato ketchup  nettle sting  bleaches
baking soda  stomach juices  detergents

Q2. The grid shows pH numbers and test colours of some solutions.

b) Identify the oxide which dissolves in water to give an alkaline solution.

You may wish to use the data booklet to help you.

c) Identify the compound which will neutralise an acid.
d) The pH number of water is on the grid. Which box is it in?

e) Write a balanced equation for the reaction of one of the chemicals you chose in a), showing the formation of the alkali.

f) Write a balanced equation for the reaction of one of the chemicals you chose in b), showing the formation of the acid.
4.2 Acid & Base Structures

**Acid Molecules**

If we look carefully at the *structures* of the substances that *dissolve in water* to produce *acidic solutions* we can see a pattern emerge.

Firstly, they are all *covalent molecules* but all have a *very polar bond* involving a *hydrogen* atom.

![Hydrogen chloride](image)

Secondly, most of these molecules have a *double covalent bond* from the central atom to an *oxygen* atom next to the *polar* $\text{O} - \text{H}$ bond.

![Hydrogen carbonate, sulfate, nitrate](image)

As a result, the *acid molecules* will be *very soluble in water*.

However, whilst water *cannot* be *electrolysed* at *low voltages*, solutions of these *acid molecules* can be *electrolysed* and always produce hydrogen gas at the negative electrode (*cathode*).

$$2\text{H}^+_{(aq)} + 2\text{e} \rightarrow \text{H}_2(g)$$

This suggests that the following *change* has taken place:

$$\text{covalent molecule} \rightarrow \text{ionic solution}$$

*Acids are substances which dissolve in water to produce hydrogen ions, $\text{H}^+_{(aq)}$.***
The strong attractions between water molecules and the acid molecules do much more than simply make them soluble in water. Water molecules are able to pull the acid molecules apart.

In the process, the shared electrons are completely transferred to the atom with the strong pull—in this case the chlorine atom. The acid molecule is ionised—turned into ions dissolved in water.

Acids are substances which dissolve in water to produce hydrogen ions, $H^+_{\text{(aq)}}$.
Ammonia, is the 'only' base that starts off as a **cov mol** but when it **dis in wa** the **solu con** showing that **io** are formed. The **pH** of the **solu** is **>** showing that it has formed an **alk** solution.

The two **pol mol att** each other **strongly enough to pull a hydr ion ( H⁺)** off the **wa molecule.**

The resulting **OH⁻ ion** makes the solution **alk**.

\[
\text{NH}_3 (g) + H_2O (l) \rightarrow \text{NH}_4^+ (aq) + OH^- (aq)
\]

A convenient way to make **amm comp** in the **lab** is to heat an ammonium **comp** with a **strong ba** or alk.  **(The reverse of the reaction above)**

**Properties of Ammonia**

Ammonia is a **co less ga** at 20 °C

Ammonia is the **only alk gas**

Ammonia has a strong **pun smell**

Ammonia is **le dense than air**

Ammonia **dis in wa** to form an **alk** solution which will **con electricity**

As the ammonia gas cools and contracts, the water is slowly sucked up the tube. As the first drop appears at the end of the tube ALL the ammonia gas dissolves in this single drop of water.

As a result, a partial vacuum exists in the flask resulting in more water being sucked in very quickly to replace the ammonia gas molecules.

A 'fountain' is the result, showing that ammonia is extremely soluble in water. This is known as the **Fountain Experiment**.
Water Ions

More surprisingly, perhaps, is the fact that *atta*ctions between *water* molecules can also result in this *covalent* molecule being pulled apart to form *ions*.

The two *polar* molecules *attact* each other *strongly* enough to pull a *hydr*ion (H\(^+\)) off one of the *water* molecules.

However an *OH* ion is also formed so water remains overall *neutral*, pH = 7.

\[
\text{Dissociation} \quad \text{H}_2\text{O}(l) \rightarrow \text{H}^+(aq) + \text{OH}^-(aq)
\]

Almost immediately, the *ions* will *atta*ct each other and the *mol* ecule will reform.

Water is a *mixture* of *mol* ecules and *ions*, constantly *bre*aking up and *ref*orming.

The vast majority of water is *mol* ecular but there are always enough *ions* to make *water* a poor conductor.

<table>

**Acids** are substances which dissolve in water to increase the concentration of *hydrogen ions*, \(\text{H}^+(aq)\) - \(\text{H}^+\) concentration > 10\(^{-7}\)

**Bases** are substances which dissolve in water to increase the concentration of *hydroxide ions*, \(\text{OH}^-(aq)\) - \(\text{OH}^-\) concentration > 10\(^{-7}\)
**Acids & Bases**

**Topic 4**

### pH Numbers

<table>
<thead>
<tr>
<th>Acid solutions</th>
<th>Base solutions</th>
</tr>
</thead>
<tbody>
<tr>
<td>pH &lt; 7</td>
<td>pH &gt; 7</td>
</tr>
<tr>
<td>Have more H⁺ ions</td>
<td>Have more OH⁻ ions</td>
</tr>
</tbody>
</table>

If you dilute an acid by adding more water, the pH will increase towards pH = 7.

It would be tempting to assume that an acid of pH = 1, eg stomach acid, was three times as concentrated as an acid of pH = 3, e.g. lemon juice.

In fact, it is 10 x 10⁷ i.e. ten times as concentrated.

For each change in pH, a solution will become ten times more concentrated or ten times less concentrated.

**Cond** devices, (H⁺ ions are good conductors), such as pH **met** and pH **pro** can also be used.
Q1.  

(a) What two features are found in most acid molecules?  
_________________________________________________________________________
_________________________________________________________________________  

(b) Which of the following is an acid molecule?

A  

\[
\begin{array}{c}
\text{H-C-O-H} \\
\text{H-C-H} \\
\text{H-H}
\end{array}
\]

B  

\[
\begin{array}{c}
\text{H-C-C-H} \\
\text{H-C-O-H} \\
\text{H-H}
\end{array}
\]

C  

\[
\begin{array}{c}
\text{H-O-C-O-H} \\
\text{H-H}
\end{array}
\]

D  

\[
\begin{array}{c}
\text{H-C-C=O} \\
\text{H-H} \\
\text{H-H}
\end{array}
\]

Q2.  

The grid shows some statements which can be applied to different solutions.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>It has a pH less than 7.</td>
</tr>
<tr>
<td>B</td>
<td>It conducts electricity.</td>
</tr>
<tr>
<td>C</td>
<td>It contains less OH&lt;sup&gt;-&lt;/sup&gt;(aq) ions than pure water.</td>
</tr>
<tr>
<td>D</td>
<td>It does not neutralise dilute hydrochloric acid.</td>
</tr>
<tr>
<td>E</td>
<td>When diluted the concentration of OH&lt;sup&gt;-&lt;/sup&gt;(aq) ions decreases.</td>
</tr>
</tbody>
</table>

Identify the two statements which are correct for an alkaline solution.

_________________________________________________________________________

Q3.  

What is the most likely pH value that would be obtained when zinc oxide is added to water?  

(A: 5  B: 7  C: 9  D: 11)

(You may wish to use page 5 of the data booklet to help you.)

Q4.  

For each of the acids below  

(a) Write the formula for the molecule  

\[
\begin{array}{c}
\text{H-O-S-O-H} \\
\text{sulphurous acid}
\end{array}
\]

(b) Write the formulae for the two ions formed when it dissolves (dissociates) in water?

\[
\text{O=N-O-H} \\
\text{nitrous acid}
\]

\[
\text{O=Cl-O-H} \\
\text{chloric acid}
\]

\[
\begin{array}{c}
\text{ions} \\
\text{molecular formula}
\end{array}
\]

Q5.  

A solution of 0·1 mol/l hydrochloric acid has a pH of 1.  

(a) What colour would universal indicator turn when added to a solution of hydrochloric acid?  

_________________________

(b) Starting at pH 1, draw a line to show how the pH of this acid changes when diluted with water.

_________________________________________________________________________

(c) Calculate the number of moles of hydrochloric acid in 50 cm<sup>3</sup> of 0·1 mol/l hydrochloric acid solution.

(d) Magnesium carbonate can be used to neutralise acid:

\[
\text{MgCO}_3(s) + 2 \text{HCl}_{(aq)} \rightarrow \text{MgCl}_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)
\]

(i) Calculate the number of moles of MgCO<sub>3</sub> needed to neutralise 50 cm<sup>3</sup> of 0·1 mol/l HCl<sub>(aq)</sub>.  

(ii) Calculate the mass of MgCO<sub>3</sub> needed to neutralise 50 cm<sup>3</sup> of 0·1 mol/l HCl<sub>(aq)</sub>.  

(You may wish to use page 5 of the data booklet to help you.)
4.3 Reactions of Acids

With Metals

As you have probably learnt in earlier courses, reactive metals that are above hydrogen in the Reactivity Series are able to react with acids.

The gas produced burns with a squeaky-plop. This shows that the gas is again hydrogen.

Reactive metals are able to force hydrogen ions to change back to hydrogen atoms. This allows the metal to take the place of the hydrogen and form a new substance called a Salt.

The sodium ion takes the place of the hydrogen ion to form the salt called sodium chloride.

Each acid has its own salts:

- hydrochloric acid, HCl → chlorides e.g. sodium chloride, NaCl
- sulfuric acid, H_2SO_4 → sulfates e.g. copper sulfate, CuSO_4
- nitric acid, HNO_3 → nitrates e.g. potassium nitrate, KNO_3

<table>
<thead>
<tr>
<th>Acid</th>
<th>+</th>
<th>metal</th>
<th>→</th>
<th>salt</th>
<th>+</th>
<th>hydrogen</th>
</tr>
</thead>
<tbody>
<tr>
<td>e.g. magnesium(s)</td>
<td>+</td>
<td>sulfuric acid</td>
<td>→</td>
<td></td>
<td>+</td>
<td>hydrogen (g)</td>
</tr>
<tr>
<td>e.g. (H^+)_2SO_4^{2-}(aq)</td>
<td>→</td>
<td>(aq)</td>
<td>+</td>
<td>(g)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

We will learn more about this reaction if we firstly write an ionic equation and then remove spectator ions.

KHS Oct 2013
**With Metal Oxides**

In *me oxi* the *me* has already formed an *io* and will not *re* any more.

The *oxi ion*, O\(^2-\), reacts with the *hydr ions* in the *ac* to form *wa*, H\(_2\)O.

This leaves the *me ion* to take the *hydr ions* place, so again a *sa* will be produced.

\[
\text{Acid} + \text{metal oxide} \rightarrow \text{salt} + \text{water}
\]

e.g. iron (III) + nitric oxide \rightarrow \text{ } + \text{water}

balanced \[
\text{Fe}_2\text{O}_3 (s) + \quad \text{(aq)} \rightarrow \quad \text{(aq)} + \quad \text{H}_2\text{O (l)}
\]

ionic \[
(s) + \quad \text{(aq)} \rightarrow \quad \text{(aq)} + \quad \text{H}_2\text{O (l)}
\]

without spectator ions \[
3 \text{O}^{2-} (s) + \quad \text{H}^+ (aq) \rightarrow \quad \text{H}_2\text{O (l)}
\]

**With Metal Carbonates**

In *me carb* the *me* has already formed an *io* and will not *re* any more.

The *carb ion*, CO\(_3^{2-}\), reacts with the *hydr ions* in the *ac* to form *wa*, H\(_2\)O and *car di* gas, CO\(_2\).

This leaves the *me ion* to take the hydrogens place, so again a *sa* will be produced.

\[
\text{Acid} + \text{metal carbonate} \rightarrow \text{salt} + \text{water} + \text{carbon dioxide}
\]

e.g. calcium + hydrochloric carbonate \rightarrow calcium + water + carbon chloride dioxide

balanced \[
\text{CaCO}_3 (s) + 2 \text{HCl (aq)} \rightarrow \text{CaCl}_2 (aq) + \quad \text{H}_2\text{O (l)} + \quad \text{CO}_2 (g)
\]

*KHS Oct 2013*  
*page 14*  
*National 5*
Acids & Bases Topic 4

 Ionic

\[ \text{CO}_3^{2-}(s) + 2 \text{H}^+(aq) \rightarrow \text{H}_2\text{O}(l) + \text{CO}_2(g) \]

Without spectator ions

\[ \text{CO}_3^{2-}(s) + 2 \text{H}^+(aq) \rightarrow \text{H}_2\text{O}(l) + \text{CO}_2(g) \]

With Alkalis

Alkalis are solutions which contain hydroxide ions.

Most alkalis are made by dissolving a metal oxide in water - though only those in Group 1 are very soluble.

\[
\begin{align*}
\text{Na}_2\text{O}(s) + \text{H}_2\text{O}(l) & \rightarrow \text{NaOH}(aq) \\
\text{K}_2\text{O}(s) + \text{H}_2\text{O}(l) & \rightarrow \text{KOH}(aq) \\
\text{CaO}(s) + \text{H}_2\text{O}(l) & \rightarrow \text{Ca(OH)}_2(aq) \\
\text{MgO}(s) + \text{H}_2\text{O}(l) & \rightarrow \text{Mg(OH)}_2(aq)
\end{align*}
\]

Soda - sodium hydroxide
Pearl ash - potassium hydroxide
Lime - calcium hydroxide
Magnesia - magnesium hydroxide

It is the hydroxide ion which will react with the hydrogen ion in the acid, and water is the product.

Acid + alkali → salt + water

e.g. sodium hydroxide + sulfuric acid → + water

\[
\begin{align*}
2 \text{NaOH}(aq) + \text{H}_2\text{SO}_4(aq) & \rightarrow \text{Na}_2\text{SO}_4(aq) + 2 \text{H}_2\text{O}(l) \\
\text{ionic} & \quad 2 \text{Na}^+\text{OH}^{-}(aq) + (\text{H}^+)_2\text{SO}_4^{2-} \rightarrow (\text{Na}^+)_2\text{SO}_4^{2-} + 2 \text{H}_2\text{O}(l)
\end{align*}
\]

Once again, the metal ion to take the hydrogens place, so again a salt will be produced. The metal ions are spectator ions as are the sulfate ions in the example above.

Without spectator ions

\[ 2\text{OH}^-(aq) + 2\text{H}^+(aq) \rightarrow 2\text{H}_2\text{O}(l) \]
Salt Preparation

Because of the large number of, in particular, metal oxides and carbonates that it is possible to react easily with a number of acids, a whole range of ‘new substances’ can be made using acid reactions. If we include, precipitation reactions (met earlier in the course) there are very few compounds that cannot be made quickly and easily.

This is basically a Problem Solving activity that will test your knowledge of acid reactions, your use of solubility tables, your appreciation of practical considerations (such as ensuring complete reaction) and your knowledge of separation techniques.

There are 3 parts to salt preparation

1) Choice of Reaction
   a) Acid + (solid) Metal
   b) Acid + (solid) Oxide, Hydroxide or Carbonate
   c) Acid + Alkali (solution)
   d) Precipitation (solutions, one of which may be acid)

2) Reaction Methods & 3) Separation of Salt produced

Solid Metals, Oxides, Hydroxides & Carbonates

The solid is added spatula by spatula, stirring all the time, until there is an obvious layer of unreacted (excess) solid lying at the bottom. The acid may need to be heated to speed up the reaction.

Alkali solutions

The acid will need to be added slowly and carefully (eventually drop by drop) until the indicator just changes colour.

Then, to another flask, the exact same volumes will be reacted but without the indicator present.

The excess solid must now be separated from the salt solution by filtering. The solid trapped in the filter paper can be discarded.

The salt solution can now be heated until all the water has evaporated away leaving solid salt powder. If preferred, the solution can be left to evaporate slowly in which case salt crystals will form.
**Precipitation reactions**

Using the Data Book, two suitable solutions will need to be made up.
Each solution will provide one half of the salt to be made.
Once made, the two solutions are simply mixed together.

Sometimes a choice of methods is available. To help choose the ‘best’ method the following summary may be useful.

<table>
<thead>
<tr>
<th>Reaction</th>
<th>'Advantages'</th>
<th>'Disadvantages'</th>
<th>'Suitability'</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>solid metals</strong></td>
<td>Easy to ensure 'complete' reaction - excess metal left over at end.</td>
<td>Must filter excess metal.</td>
<td>Not suitable if salt is insoluble - too difficult to separate from excess solid metal.</td>
</tr>
<tr>
<td><strong>solid oxides, hydroxides, carbonates</strong></td>

</tbody>
</table>

**Examples**

To prepare copper sulfate

1. The Data Book will tell you that copper sulfate is soluble, so precipitation is out.
2. Acid to use: - sulfuric acid
3. Copper metal - no reaction with acid.
4. Copper oxide/hydroxide is insoluble so there is no alkali solution, so titration is out.
5. Best method would be to add solid copper oxide/hydroxide/carbonate to sulfuric acid.

To prepare zinc chloride

1. The Data Book will tell you that zinc chloride is soluble, so precipitation is out.
2. Acid to use: - hydrochloric acid
3. Zinc reacts slowly with acid.
4. Zinc oxide/hydroxide is insoluble so there is no alkali solution, so titration is out.
5. Best method would be to add solid zinc or zinc oxide/hydroxide/carbonate to hydrochloric acid.

To prepare silver chloride

1. The Data Book will tell you that silver chloride is insoluble, so precipitation is the best method.
2. Use the Data Book to find a soluble silver compound eg silver nitrate.
Use the Data Book to find a soluble chloride compound eg sodium chloride.
Acids & Bases

Q1.

The grid shows the names of some metals.

A | silver
B | sodium
C | magnesium
D | nickel
E | lead
F | iron

Identify the metal that does not react with dilute acid.
You may wish to use page 7 of the data booklet to help you.

Q2.

Copy and complete the following equations

**lithium** + **hydrochloric** → + **water**
**hydroxide** **acid**

**aluminium** + **nitric** → + **water**
**oxide** **acid**

**strontium** + **nitric** → + **water**
**carbonate** **acid**

**zinc** + **sulphuric** → +

Q3.

Copy, complete and balance the following equations

Ca(OH)₂ + **HCl** → + H₂O

CuO + → Cu(NO₃)₂ +

+ H₂SO₄ → K₂SO₄ + + CO₂

Li + → LiCl +

Q4.

Lead(II) nitrate solution reacts with potassium iodide solution to give a yellow solid.

\[
Pb^{2+}(aq) + 2NO_3^-(aq) + 2K^+(aq) + 2I^-(aq) \rightarrow PbI_2(s) + 2K^+(aq) + 2NO_3^-(aq)
\]

Identify the **two** spectator ions in the reaction.

Q5.

The grid shows the names of some soluble compounds.

A | sodium iodide
B | potassium chloride
C | lithium chloride
D | barium bromide
E | sodium hydroxide
F | potassium sulphate

a) Identify the base. ___________

b) Identify the two compounds whose solutions would form a precipitate when mixed.
You may wish to use the data booklet to help you.

_________ and __________

Q6.

Copy and complete the following equations, clearly showing which of the products is the **precipitate**.

BaCl₂ (aq) + K₂SO₄ (aq) → +

CuSO₄ (aq) + Na₂CO₃ (aq) → +

AgNO₃ (aq) + KCl (aq) → +

Q7.

Reactions can be represented using ionic equations. Which ionic equation shows a neutralisation reaction?

A \[2H_2O(l) + O_2(g) + 4e^{-} \rightarrow 4OH^-(aq)\]

B \[H^+(aq) + OH^-(aq) \rightarrow H_2O(l)\]

C \[SO_2(g) + H_2O(l) \rightarrow 2H^+(aq) + SO_3^{2-}(aq)\]

D \[NH_4^+(s) + OH^-(s) \rightarrow NH_3(g) + NH_4^+(s)\]

Q8.

A solution of sulphuric acid can be used to neutralise a solution of sodium hydroxide.

a) What is the pH of the solution when it is exactly neutral. ___________

b) What is the name of the salt formed in the neutralisation reaction? ___________

c) Balance the following equation for the reaction.

\[(H^+)₂SO_4^{2-} + Na^+OH^- \rightarrow (Na^+)₂SO_4^{2-} + H₂O\]

d) Rewrite the equation, omitting the spectator ions.

+ →

KHS Oct 2013

National 5
4.4 Quantitative Analysis

Titrations

It is quite common for a Chemist to be asked to measure how much acid or alkali is present in a solution - for example, how much acid is present in lemonade.

A technique called titration is used, and you may be expected to demonstrate your ability to carry out a titration.

A carefully measured volume of the lemonade would be placed in the flask. An indicator that will change colour is also added.

An alkali whose concentration is accurately known would be placed in a burette, and then added to the flask.

Eventually the alkali would be added drop by drop until the indicator changes colour to show that the acid in the lemonade has been neutralised.

Before the alkali can be used to determine how much acid is present in the lemonade, it must be standardised - titrated against a Standard Solution of a suitable acid, such as potassium hydrogen phthalate (KHP).

An unusual acid like this is chosen because it is extremely stable, very soluble and can be made to a very high level of purity.

An analytical balance is used to very accurately weigh out a calculated mass of the chemical.

From this mass, the number of moles of chemical can be calculated and used to calculate the concentration of the solution made.
1. Set up the burette carefully in a stand. Clamp gently!

2. Collect a beakerful of the alkali you are going to use and another empty waste beaker.

3. Pour just a little of the alkali into the burette to rinse it. Pour it out into your waste beaker.

4. With the valve closed, fill up the burette to just above the zero line. Then remove the funnel.

5. Open the valve slightly and let the alkali drip into your waste beaker until the bottom of the curved surface is on or below the zero line.

6. Read your starting volume. Read with your eye level with the curved surface. Make a note of this reading. The burette is now ready for use.

**Technique - Standardisation of alkali (NaOH)**

\[
\text{mass of KHP} = 10.00 \text{ g} \\
\text{g} \quad \rightarrow \quad 1 \text{ mole} \\
10.00 \text{ g} \quad \rightarrow \quad 1 \times 10.00 \\
= \text{ moles}
\]

\[
\text{vol of flask} = 500 \text{ ml} = 0.5 \text{ l} \\
C = \frac{n}{V} \\
= \frac{10.00}{0.5} \\
= 0.098 \text{ mol l}^{-1}
\]
2. **Using the pipette**  
The *pip* is used to accurately measure out the same *vol* of *KHP* every time.

1. Collect a *bea ful* of the *KHP* you are going to use, and a conical *fla*.
2. Use the *fil* to suck the *KHP* above the fill mark.
3. Holding the *pip* above the beaker, slowly let the *KHP* drip out until the *bot* of the *cur surface* is on the fill mark.
4. Carefully transfer the *KHP* in the *pip* into your flask.
5. Add a few drops of *indi*.

3. **Doing the Titration**  
The aim is to find out exactly what *vol* of *alkali* is needed to *neut* the *known vol* of *KHP*.

1. Put a piece of *wh paper* under the *fla*. It will help you to see the *col* of *indi*.
2. Start by adding the *alkali* 5 ml at a time. You should see the *indi col* change but then return quickly.
3. If the *col* takes longer to return, add less *alkali* next time. Ideally you should add *one drop* of *alkali* and see the *indi* change permanently.
4. Write down the fin bur reading to at least the nearest 0.1 ml.

Remember that a bur reads d wards.

The bur opposite is reading ml (and not ml).

5. You will now need to rep your titr with a freshly pip sample of KHP.

Knowing the ans from the first atte should allow you to qui add enough alkali to nearly neutr the potassium hydrogen phthalate. Then you can add more alkali dr by dr to get an acc result.

Results

6. You should record your results in a table similar to the one on the right.

<table>
<thead>
<tr>
<th>Attempt number</th>
<th>Starting volume (ml)</th>
<th>Final volume (ml)</th>
<th>Volume added (ml)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.1</td>
<td>22.0</td>
<td>21.9</td>
</tr>
<tr>
<td>2</td>
<td>22.0</td>
<td>43.5</td>
<td>21.5</td>
</tr>
<tr>
<td>3</td>
<td>0.2</td>
<td>21.9</td>
<td>21.7</td>
</tr>
<tr>
<td>4</td>
<td>21.9</td>
<td>42.6</td>
<td>21.7</td>
</tr>
</tbody>
</table>

You have to continue repeating the titr until you get two results at least within 0.1 ml of each other.

7. You should finish off by quoting your conclusion in terms of:

“It takes 21.7 ml of NaOH to neutralise 20 ml of KHP”.

If you have two, or more, answers close to each other then it may be better to use their average as your final answer.

To get similar results each time, (the aim of this technique), you will need to work hard to ensure that you pipette exactly the same volume of potassium hydrogen phthalate each time.
As part of the Assessment Task 1, you will be asked to evaluate experimental procedures, mentioning at least one of the below.

- **effectiveness of procedure**
  
  the effectiveness of a titration, for example, can often be determined by:
  
  *how often you had to repeat the titration?*  *how was the colour change (1 drop)?*  
  *how close to each other were your volumes?*

- **control of variables**
  
  how well did you control variables such as:
  
  *concentration of NaOH, volume of KHP, amount of indicator added etc?*

- **limitations of equipment**
  
  any issues with equipment such as:
  
  *electronic balance (2 or 3 decimal place?), volumetric flasks (A or B grade?),*
- sources of uncertainty

these are often 'built-in errors' such as:
weighings (± ? g), volumetric flasks (± ? cm³), pipettes (± ? cm³), burettes (± ? cm³), burette readings (± ? cm³) etc - we often express these as % errors.

- possible improvements

these will often emerge from the previous categories:
Q1.

The table below shows the colours of various indicators at different pH values.

<table>
<thead>
<tr>
<th>indicator</th>
<th>pH 1</th>
<th>colour 1</th>
<th>pH 2</th>
<th>colour 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>bromophenol blue</td>
<td>3</td>
<td>yellow</td>
<td>4.5</td>
<td>blue</td>
</tr>
<tr>
<td>phenolphthalein</td>
<td>8</td>
<td>colourless</td>
<td>10</td>
<td>pink</td>
</tr>
<tr>
<td>methyl orange</td>
<td>3</td>
<td>red</td>
<td>4.5</td>
<td>yellow</td>
</tr>
<tr>
<td>thymol blue</td>
<td>6</td>
<td>yellow</td>
<td>7.5</td>
<td>blue</td>
</tr>
</tbody>
</table>

The table below shows the pH of some solutions.

<table>
<thead>
<tr>
<th>solution</th>
<th>pH</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.1 M hydrochloric acid</td>
<td>1.0</td>
</tr>
<tr>
<td>0.1 M ethanoic acid</td>
<td>5.0</td>
</tr>
<tr>
<td>0.1 M ammonia</td>
<td>10.0</td>
</tr>
<tr>
<td>0.1 M sodium hydroxide</td>
<td>12.5</td>
</tr>
</tbody>
</table>

**a)** Complete the table below to show the colours of the indicators in the solutions.

<table>
<thead>
<tr>
<th>indicator</th>
<th>solution</th>
<th>colour</th>
</tr>
</thead>
<tbody>
<tr>
<td>bromophenol blue</td>
<td>0.1 M hydrochloric acid</td>
<td></td>
</tr>
<tr>
<td>phenolphthalein</td>
<td>0.1 M ethanoic acid</td>
<td></td>
</tr>
<tr>
<td>methyl orange</td>
<td>0.1 M ammonia</td>
<td></td>
</tr>
<tr>
<td>thymol blue</td>
<td>0.1 M sodium hydroxide</td>
<td></td>
</tr>
</tbody>
</table>

**b)** Name one indicator which turns the same colour in both ethanoic acid and sodium hydroxide.

**c)** Which two indicators turn the same colour in hydrochloric acid.

Q2.

One of the solids often used in Antacid Tablets to treat indigestion is magnesium hydroxide.

A pupil decided to find out how much of the solid would be needed to neutralise some acid.

**a)** Complete the equation for the reaction of magnesium hydroxide with hydrochloric acid

\[ \text{Mg(OH)}_2 (\text{aq}) + 2\text{HCl} (\text{aq}) \rightarrow \text{H}_2\text{O} (\text{l}) \]

**b)** Calculate the *number of moles* of HCl present.

**c)** Calculate the *number of moles* of Mg(OH)_2 needed.

**d)** Calculate the *mass* of Mg(OH)_2 needed.
Knowledge Met in this Topic

Common household acids and alkalis

- **Acids**: vinegar, citrus fruits, cola drinks etc
- **Alkalis**: lime, oven cleaner, bleach, bicarbonate of soda, soap, ammonia

Oxides and hydroxides

- Oxides of **non-metals** which dissolve produce **acidic** solutions e.g. $\text{CO}_2$, $\text{SO}_2$ and $\text{NO}_2$.
- Non-metal oxides are the main cause of **acid rain**.
- Oxides and hydroxides of **metals** which dissolve produce **alkaline** solutions.
- All the oxides of Group 1 metals are very soluble, only some from Group 2 are soluble.

Important acids

- Most acids start off as **covalent molecules** which break apart (**dissociate**) in water to produce **hydrogen ions**, $\text{H}^+$ \text{(aq)}.
- **hydrochloric** acid $\text{HCl}$: $\text{H}^+$ \text{(aq)} + $\text{Cl}^-$ \text{(aq)}
- **sulphuric** acid $\text{H}_2\text{SO}_4$: $\text{H}^+$ \text{(aq)} + $\text{SO}_4^{2-}$ \text{(aq)}
- **nitric** acid $\text{HNO}_3$: $\text{H}^+$ \text{(aq)} + $\text{NO}_3^-$ \text{(aq)}

The pH scale

- pH is a number that shows how acidic or alkaline a solution is.
- Universal indicator, pH paper or a pH meter can show the pH of a solution.
- **Acids**: pH less than 7, pH < 7
  **Neutral**: pH equals 7, pH = 7
  **Alkalis**: pH more than 7, pH > 7
- When acids dissolve in water they produce hydrogen ions, $\text{H}^+$ \text{(aq)}
- When alkalis dissolve in water they produce hydroxide ions, $\text{OH}^-$ \text{(aq)}
- Pure water and all neutral solutions contain a tiny but equal concentration of hydrogen and hydroxide ions, $\text{H}^+$ \text{(aq)} = $\text{OH}^-$ \text{(aq)}
- An acid solution contains more hydrogen ions than hydroxide, $\text{H}^+$ \text{(aq)} > $\text{OH}^-$ \text{(aq)}
- An alkali solution contains less hydrogen ions than hydroxide, $\text{H}^+$ \text{(aq)} < $\text{OH}^-$ \text{(aq)}
- Diluting acids or alkalis will reduce the concentration of $\text{H}^+$ \text{(aq)} and $\text{OH}^-$ \text{(aq)} and move the pH towards 7.

Neutralisation

- **Neutralisation** is a reaction in which the pH of a solution moves towards 7.
Everyday examples of neutralisation

- Lime (calcium oxide) is used to reduce acidity in soil and water.
- Cures for acid indigestion contain neutralisers such as calcium carbonate.

Bases and alkalis

- A base is a substance that neutralises an acid.
- An alkali is a base that dissolves in water.

Salts

- Salts are ionic compounds formed in reactions between acids and neutralisers.
- A metal ion or an ammonium ion will have replaced the hydrogen in an acid.
- Hydrochloric acid $\text{HCl}$ forms chlorides e.g. NaCl
  Sulphuric acid $\text{H}_2\text{SO}_4$ forms sulphates e.g. CuSO$_4$
  Nitric acid $\text{HNO}_3$ forms nitrates e.g. NH$_4$NO$_3$
- All the oxides of Group 1 metals are very soluble, only some from Group 2 aresoluble.

Acid Reactions

- Acid + Alkali $\rightarrow$ Water $+$ ‘salt’
  $\text{eg} \quad \text{H}^+ \text{Cl}^- + \text{Na}^+ \text{OH}^- \rightarrow \text{H}_2\text{O} + \text{Na}^+ \text{Cl}^-$
  removing spectator ions:- $\text{H}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O}$
- Acid + Metal $\rightarrow$ Hydrogen $+$ ‘salt’
  $\text{eg} \quad (\text{H}^+)_2\text{SO}_4^{2-} + \text{Mg} \rightarrow \text{H}_2 + \text{Mg}^{2+} \text{SO}_4^{2-}$
  removing spectator ions:- $2\text{H}^+ + \text{Mg} \rightarrow \text{H}_2 + \text{Mg}^{2+}$
- Acid + Oxide/Hydroxide $\rightarrow$ Water $+$ ‘salt’
  $\text{eg} \quad 2\text{H}^+ \text{NO}_3^- + \text{Cu}^2+ \text{O}^{2-} \rightarrow \text{H}_2\text{O} + \text{Cu}^2+ (\text{NO}_3^-)_2$
  removing spectator ions:- $2\text{H}^+ + \text{O}^{2-} \rightarrow \text{H}_2\text{O}$
- Acid + Carbonate $\rightarrow$ Water $+$ Carbon dioxide $+$ ‘salt’
  $\text{eg} \quad 2\text{H}^+ \text{Cl}^- + \text{Ca}^{2+} \text{CO}_3^{2-} \rightarrow \text{H}_2\text{O} + \text{CO}_2 + \text{Ca}^{2+} (\text{Cl})_2$
  removing spectator ions:- $2\text{H}^+ + \text{CO}_3^{2-} \rightarrow \text{H}_2\text{O} + \text{CO}_2$
- Acid rain reacts with carbonate rocks such as marble (statues) and limestone, and with metals such as iron.
- Reacting acids is a good way of making salts.
- Salts can also be made by precipitation.
Ammonia

- Ammonia is a colourless gas with a sharp, unpleasant (pungent) smell.
- Ammonia is a very soluble in water producing an alkaline solution.

\[ \text{NH}_3 + \text{H}_2\text{O} \rightarrow \text{NH}_4^+ + \text{OH}^- \]
- Ammonia is the only common alkaline gas.
- Ammonia can neutralise an acid and form an ammonium salt.

\[ \text{NH}_3 + \text{H}_2\text{SO}_4 \rightarrow (\text{NH}_4)_2\text{SO}_4 \text{ (ammonium sulphate)} \]
- Ammonia gas can be produced when an ammonium salt is heated with an alkali e.g. \[ \text{NH}_4\text{Cl} + \text{NaOH} \rightarrow \text{NaCl} + \text{H}_2\text{O} + \text{NH}_3 \]

Calculations (separate Calculations booklet)

- Knowing the formula for a substance, the Formula Mass can be calculated using relative atomic masses using values contained in the Data Booklet.
- The mass of 1 mole of a substance is equal to the Formula Mass expressed in grammes - the gramme formula mass (gfm).
- The mass of any number of moles of a chemical can be calculated:

\[ \text{mass} = \text{no. of moles} \times \text{gfm} \]
- The number of moles in any mass of a chemical can be calculated:

\[ \text{no. of moles} = \frac{\text{mass}}{\text{gfm}} \]
- Calculations involving solutions must have volumes expressed in litres.

\[ \text{concentration} = \frac{\text{no. of moles}}{\text{volume}} \]

\[ \text{no. of moles} = \text{concentration} \times \text{volume} \]
- Titration calculations can be done in steps or by using formulae such as:

\[ C_{\text{ACID}} \times V_{\text{ACID}} \times p_{\text{ACID}} = C_{\text{ALK}} \times V_{\text{ALK}} \times p_{\text{ALK}} \]

where \( p \) = 'power' of the acid \( (H^+) \) or alkali \( (OH^-) \)

\[ \frac{C_{\text{ACID}} \times V_{\text{ACID}}}{n_{\text{ACID}}} = \frac{C_{\text{ALK}} \times V_{\text{ALK}}}{n_{\text{ALK}}} \]

where \( n \) = number of moles in the balanced equation
Q1. Below is information about six chemicals.

Use the table to write the letter of the chemical substance which:

a) forms the most strongly acidic solution ______  e) is a carbonate ______
b) forms a neutral solution ______  f) is water ______
c) is a metal ______  g) is sulphur dioxide ______
d) forms a solution which turns pH paper orange ______

Q2. Equations are used to represent chemical reactions.

\[
\begin{align*}
A & : \text{Zn}(s) \rightarrow \text{Zn}^{2+}(aq) + 2e^- \\
B & : \text{C}_2\text{H}_5\text{OH}(l) + \text{O}_2(g) \rightarrow 2\text{CO}_2(g) + 3\text{H}_2\text{O}(l) \\
C & : \text{SO}_2(g) + \text{H}_2\text{O}(l) \rightarrow 2\text{H}^+(aq) + \text{SO}_4^{2-}(aq) \\
D & : \text{H}^+(aq) + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l) \\
E & : \text{SO}_3^{2-}(aq) + 2\text{H}^+(aq) + 2e^- \rightarrow \text{SO}_4^{2-}(aq) + \text{H}_2\text{O}(l)
\end{align*}
\]

a) Identify the equation which represents the formation of acid rain.
____________________________

b) Identify the equation which involves \text{sulphuric acid}.
____________________________

Q3. Reactions can be represented using ionic equations. Which ionic equation shows a neutralisation reaction?

\[
\begin{align*}
A & : 2\text{H}_2\text{O}_2_{(l)} + \text{O}_2_{2(g)} + 4e^- \rightarrow 4\text{OH}^-_{(aq)} \\
B & : \text{H}^+_{(aq)} + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l) \\
C & : \text{SO}_2_{(g)} + \text{H}_2\text{O}_{(l)} \rightarrow 2\text{H}^+_{(aq)} + \text{SO}_4^{2-}_{(aq)} \\
D & : \text{NH}_4^+_{(s)} + \text{OH}^-_{(s)} \rightarrow \text{NH}_3_{(g)} + \text{NH}_4^+_{(s)}
\end{align*}
\]

Q4. The grid shows some ions.

\[
\begin{array}{ccc}
A & \text{Al}^{3+} & \text{B} \\
\text{C} & \text{Cl}^- & \text{C} \\
\text{D} & \text{H}^+ & \text{E} \\
\text{F} & \text{F} & \text{OH}^-
\end{array}
\]

a) Identify the two ions which combine to form an insoluble compound.
____________________________

You may wish to use the data booklet to help you.

b) Identify the ion present in all alkaline solutions.
____________________________

Q5. Lead(II) nitrate solution reacts with potassium iodide solution to give a yellow solid.

\[
\text{Pb}^{2+}_{(aq)} + 2\text{NO}_3^-(aq) + 2\text{K}^+_{(aq)} + 2\text{I}^-_{(aq)} \rightarrow \text{PbI}_2_{(s)} + 2\text{K}^+_{(aq)} + 2\text{NO}_3^-(aq)
\]

Identify the two spectator ions in the reaction.
____________________________
CONSOLIDATION QUESTIONS

Q1 Both ammonia molecules and hydrogen chloride molecules are described as being polar.

a) What is meant by the word polar, as used in this context.

b) Complete the formula for hydrogen chloride to show its polar characteristics.

\[ \text{H} \quad \text{—} \quad \text{Cl} \]

c) Ammonia gas \( \text{NH}_3(\text{g}) \), can be dissolved in water to form concentrated ammonia solution. Hydrogen chloride gas \( \text{HCl}(\text{g}) \), can be dissolved in water to form concentrated hydrochloric acid.

If both bottles are placed next to each other in a fume cupboard and the stoppers removed, both liquids evaporate and a white cloud is formed where the two gases meet.

i) State the colour of the pH paper at X and Y.

pH paper X _______ pH paper Y _______

ii) The white cloud appears because the gases react to form a salt. Name the salt formed.

______________________________________________________________
**CONSOLIDATION QUESTIONS**

**Q1** A student investigated the reaction between dilute sulphuric acid and sodium carbonate.

His experiment involved determining the concentration of sodium carbonate solution by titration.

The results showed that 20 cm$^3$ of sulphuric acid was required to neutralise the sodium carbonate solution.

**a)** Calculate the number of moles of sulphuric acid in this volume.

\[
\text{\underline{\text{mol}}} 
\]

**b)** One mole of sulphuric acid reacts with one mole of sodium carbonate.

Using your answer from part \(a\), calculate the concentration, in mol/l, of the sodium carbonate solution.

\[
\text{\underline{\text{mol/l}}} 
\]

**c)** Name the salt produced when dilute sulphuric acid reacts with sodium carbonate.

_________________________________________________________________________
